

Module 3: Designing APIs

Spec driven development

- We discussed in the last modules about the benefits of designing an API first before actually building it
- This is often referred to as spec driven development
 - A development process where your application is built in two distinct phases
 - The creation of a spec (the design phase)
 - Development of code to match the spec (the development phase)
- In this module, we'll
 - Create this API specification using a standardized API description language (RAML)
 - Then learn to test it with users without writing any code

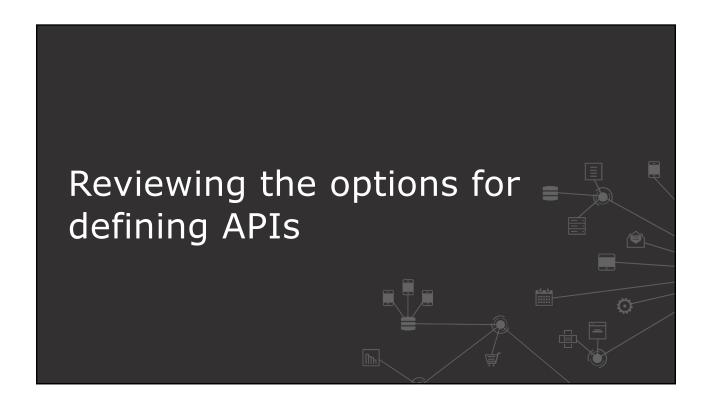

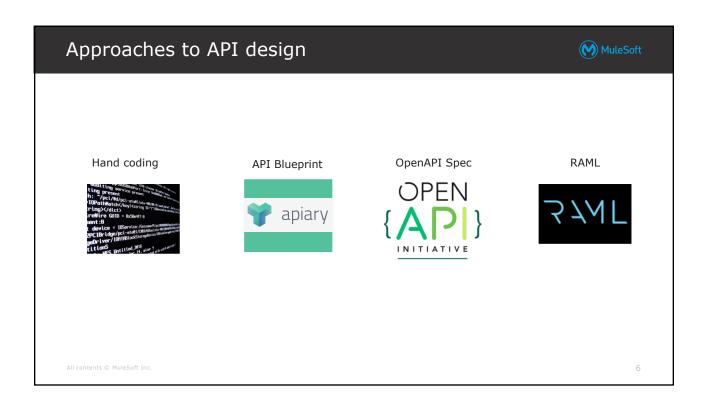

At the end of this module, you should be able to

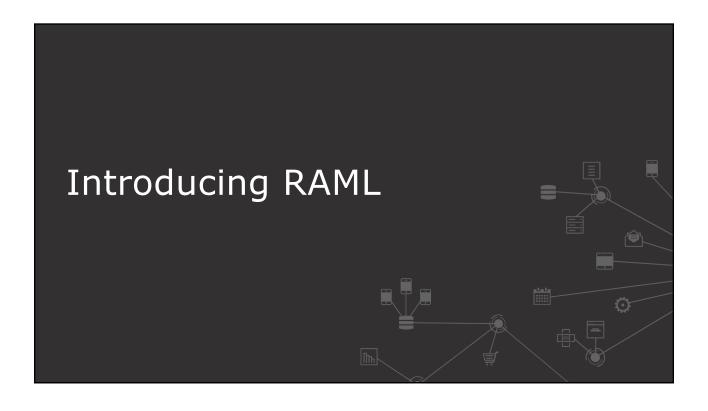

- Define APIs with RAML, the Restful API Modeling Language
- Mock APIs to test their design before they are built
- Make APIs discoverable by adding them to the private Anypoint Exchange
- Create public API portals for external developers

RAML: RESTful API Modeling Language

 A simple, structured, and succinct way of describing RESTful APIs

- A non-proprietary, vendor-neutral open spec
- Developed to help out the current API ecosystem
 - Encourages reuse, enables discovery and pattern-sharing, and aims for merit-based emergence of best practices
- RAML files can be used to auto-generate documentation, mocked endpoints, interfaces for API implementations, and more!

All contents © MuleSoft In

RAML syntax

- RAML is based on broadly-used standards such as YAML and JSON
- Uses a human-readable data serialization format where data structure hierarchy is specified by indentation

```
    Not additional markup characters
```

```
#%RAML 1.0
     version: v1
     title: American Flights API
     /flights:
 6
7
       post:
                Notice the indentation used to
8
                specify to what each line applies
9
       /{ID}:
10
        get:
11
         delete:
12
         put:
13
           responses:
14
            200:
15
              bodv:
                                                 9
                application/json:
```

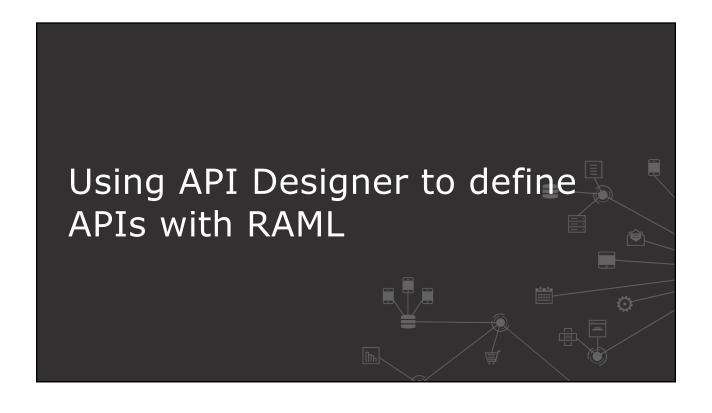

Defining resources and methods

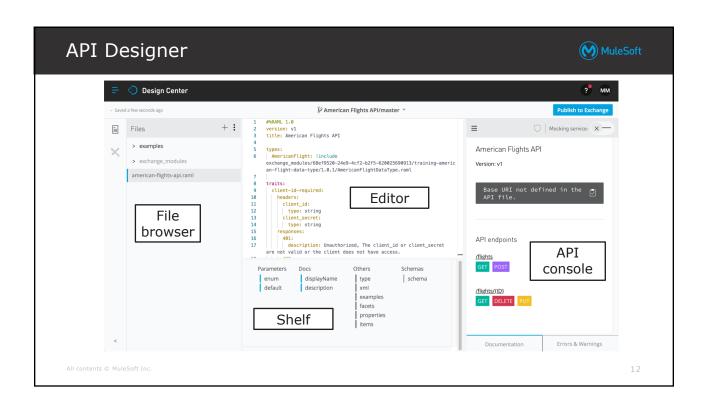

- Resources are the objects identified by the web service URL that you want to act upon using the HTTP method used for the request
- · All resources begin with a slash
- Any methods and parameters nested under a resource belong to and act upon that resource
- Nested resources are used for a subset of a resource to narrow it
 - URI parameter are enclosed in {}

```
#%RAML 1.0
     version: v1
3
     title: American Flights API
4
5
     /flights:
6
       get:
7
       post:
8
9
       /{ID}:
10
         aet:
11
         delete:
12
13
            responses:
14
              200:
15
                body:
16
                  application/json:
```

Walkthrough 3-1: Use API Designer to define an API with RAML • Define resources and nested resources • Define get and post methods • Specify query parameters • Interact with an API using the API console | Parentum Figure API Service | Parentum

Defining method response details with RAML MuleSoft Responses must be a map of one or more HTTP status codes • For each response, specify possible return data types along with descriptions and examples responses: 200: body: application/json: type: AmericanFlight examples: output: ID: 1 code: ER38sd price: 400 departureDate: 2017/07/26 origin: CLE destination: SFO emptySeats: 0 type: Boeing 737 totalSeats: 150 18

Defining method request details with RAML

 For a request, similarly specify the possible request data types along with data types, descriptions, and examples

```
/flights:
 get: --
 post:
     application/json:
       type: AmericanFlight
       examples:
         input:
           code: ER38sd
           price: 400
           departureDate: 2017/07/26
           origin: CLE
           destination: SFO
           emptySeats: 0
           plane:
             type: Boeing 737
             totalSeats: 150
```

19

Specifying examples

- There are two optional facets you can use to specify example data:
 example and examples
- Use example to represent a single instance of the data
- Use examples to represent multiple instances of the data as a map of key-value pairs

type: User
example:
 name: Bob
 lastname: Marley

type: User
examples:
 person1:
 name: Paul
 lastname: McCartney
person2:
 name: Lady
 lastname: Gaga

Modularizing APIs

- Instead of including all code in one RAML file, you can modularize it and compose it of reusable fragments
 - Data types, examples, traits, resource types, overlays, extensions, security schemes, documentation, annotations, and libraries
- Fragments can be stored
 - In different files and folders within a project
 - In a separate API fragment project in Design Center
 - In a separate RAML fragment in Exchange

All contents © MuleSoft Inc.

21

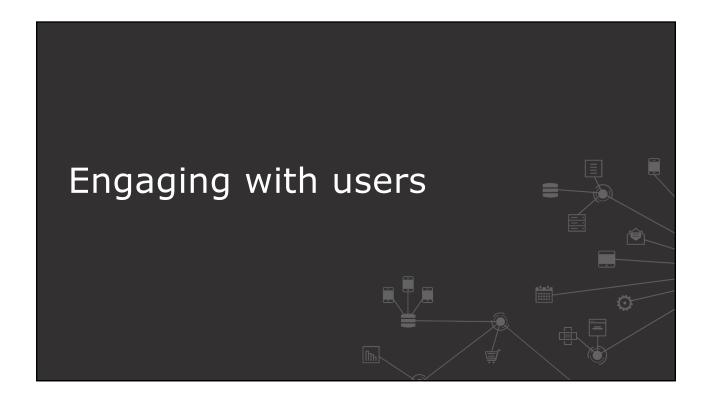

Walkthrough 3-3: Add request and response details

- Use API fragments from Exchange
- Add a data type and use it to define method requests and responses
- Add example JSON requests and responses
- Test an API and get example responses

Engaging users during the API design phase

- To build a successful API, you should define it iteratively
 - Get feedback from developers on usability and functionality along the way
- To do this, you need to provide ways for developers to discover and play with the API
- Anypoint Platform makes this easy with API portals in Exchange
 - In **private Exchange** for internal developers
 - In a **public portal** for external developers

Publishing RAML APIs to Anypoint Exchange

 You publish RAML API Specifications and RAML fragments to the Exchange from API Designer

- Not from Exchange itself

- API portals are automatically created for REST APIs added to Exchange
 - An API console for consuming and testing APIs
 - An automatically generated API endpoint that uses a mocking service to allow the API to be tested without having to implement it
- API portals can be shared with both internal and external users

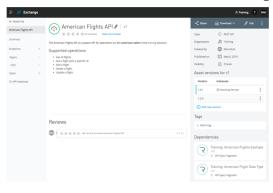

All contents @ MuleSoft Inc.

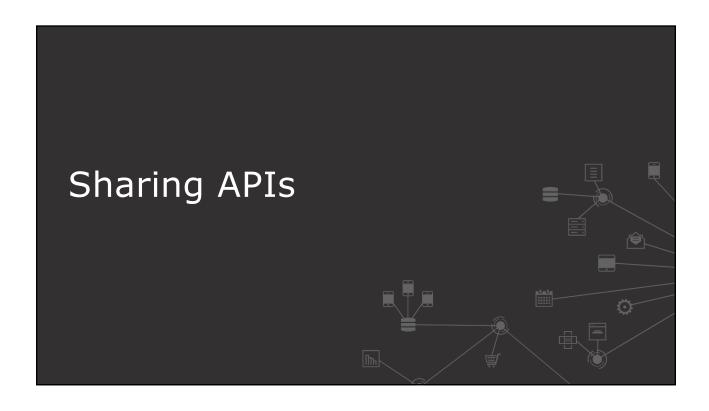

2.5

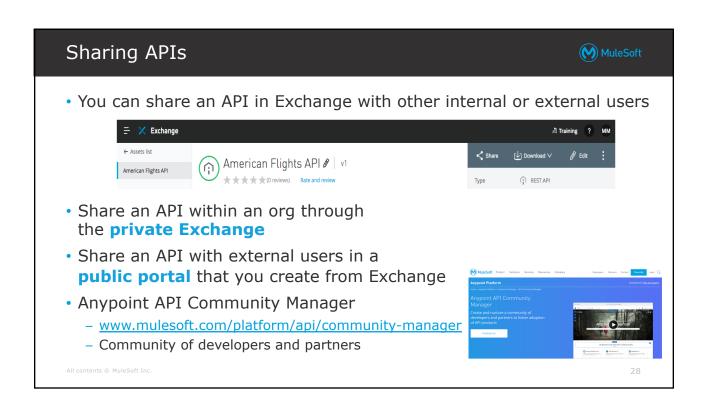

Walkthrough 3-4: Add an API to Anypoint Exchange

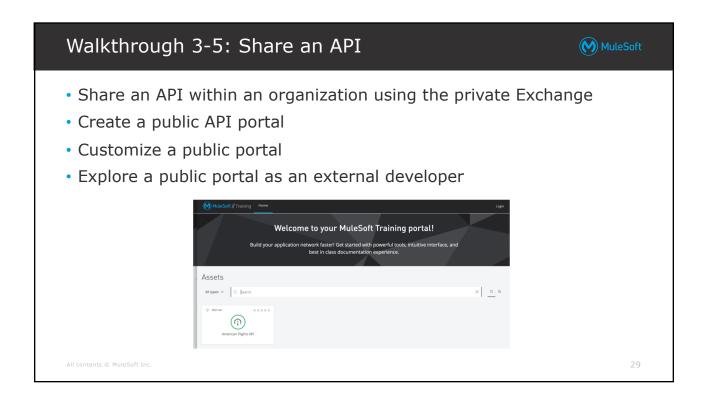

- Publish an API to Exchange from API Designer
- Review an auto-generated API portal in Exchange and test the API
- Add information about an API to its API portal
- Create and publish a new API version to Exchange

Summary

- RAML is a non-proprietary, standards-based API description language spec that is simple, succinct, and intuitive to use
 - Data structure hierarchy is specified by indentation, not markup characters
- Use API Designer to write API specifications with RAML
- Documentation is auto-generated from a RAML file and displayed in an API console
- A mocking service can be used in API console to test an API and return the example data specified in RAML

All contents @ MuleSoft Inc.

3.1

Summary

- Make an API discoverable by adding it to your private Exchange
- API portals are automatically created for the APIs with
 - Auto-generated API documentation
 - An **API console** that provides a way to consume and test an API
 - An automatically generated API endpoint that uses a mocking service to allow the API to be tested without having to implement it
- API portals can be shared with both internal and external users
 - Selectively share APIs in your org's private Exchange with other internal developers
 - Share APIs with external developers by creating and customizing a public portal from Exchange and specifying what APIs you would like to include in it
